

ABSTRACT OF THE DISCLOSURE

[0027] Multiple entries in a table are selected or deselected by designating a particular data field of a first entry. The selection state of other entries, the content of whose corresponding data field matches that of the first entry, is toggled. The data field may be designated by selecting a data field designation glyph in a web interface, by mouse-selecting a data field with a unique keyboard and/or mouse input, or by directing the table focus to a data field and entering a unique keyboard and/or mouse input. The desired entries need not be contiguous, and need not be visibly displayed in the table.
